(54) Title: **DROP-BY-DROP IRRIGATION HOSE HAVING INTERNAL DRIPPING ELEMENTS**

(57) Abstract: A drop-by-drop irrigation hose (1) of plastic having internal box-like dripping elements (2) of plastic thermo-welded to said hose (1) and provided with a single filter (4) in communication through a meandering flow path (6) and a branched channel (8) with a number of discharging chambers (5) which latter are all in turn in communication with the hose external environment by means of one or more holes (9). The dripping elements have a strip-like configuration and the perforation of all provided discharging chambers (5) takes place during the extrusion process of said irrigation hose (1). Should one discharging chamber (5) become clogged so the irrigation can continue with the other discharging chamber/chambers (5).

5

“DROP-BY-DROP IRRIGATION HOSE HAVING INTERNAL
DRIPPING ELEMENTS”

10

Field of the invention

The present invention relates to a drop-by-drop irrigation hose
having internal dripping elements for the so-called “drop-by-drop”
15 irrigation of plots of land according to the preamble of claim 1 and
dripping elements according to the preamble of claim 4.

Background of the invention

As is known, drop-by-drop irrigation hoses and the dripping
20 elements therefor consists of plastic, and said dripping elements are
thermo-welded with the internal surface of said irrigation hose at a
regular pitch during the hose extrusion.

A known drop-by-drop irrigation hose having internal dripping
elements of this type is disclosed in the IT-A-1,255,120 in which
25 three embodiments of said dripping elements are shown and
claimed, and more precisely:

a) a first embodiment (Figures 1 to 4) in which the dripping
elements have a cylindrical body on the external surface thereof are
provided two diametrically opposed equal conformations
30 comprising each a filter-like perforated zone from which a winding
flow path leads to a discharging chamber which is in
communication with the external environment through one or more

small holes in the hose wall.

b) A second embodiment (Figures 5 to 8) having a body as a cylinder sector which covers about one third of the internal hose circumference. Two filter zones and two discharging chambers
5 connected with said filter zones through two winding flow paths are provided, wherein said discharging chambers and filter zones are placed at the ends of said dripping elements and said flow paths are provided parallel to the longitudinal dripping element axis.

c) The third embodiment (Figures 9 and 10) relates to a dripping
10 element which is formed by two diametrically opposite dripping elements of the type b) which are spaced by two cylindrical sectors having a massive wall.

Said three embodiments a), b) and c) have the common feature to provide in each dripping element two equal hydraulic circuits
15 having a central flow path in communication, at one end, with a filter zone and, at the other end, with a discharging chamber.

According to the teaching of IT-A-1,255,120 only one discharging chamber is perforated, that is in communication with the external environment by means of one or more holes whereas the second
20 discharging chamber is a blind chamber which is to be manually perforated by a countryman during the use of the irrigation hose. More particularly, the perforation of said blind discharging chamber will be made by a countryman on the spot by means of a punch when the latter during surveillance inspections on the land notice
25 that a land area near a plant to be watered is dry. Such drop delivering interruptions are due, for example, to a clogging of the filter or flow path of the first discharging chamber.

Summary of the invention

30 Accordingly, the chief aim of the present invention is to provide a drop-by-drop irrigation hose having internal dripping elements which are more reliable with respect to clogging risks, and are able

to accomplish an efficient self-cleaning action of the flow path of said dripping elements as well as to increase the area of the watered surface.

Another aim of the present invention is to suggest a smaller and lighter dripping element structure so that the manufacturing costs thereof may be reduced.

Still another aim of the present invention is to avoid that a plant may die or may be damaged because a discharging chamber becomes clogged, and to drastically reduce above mentioned surveillance inspections.

The above mentioned aims are achieved according to the present invention by a drop-by-drop irrigation hose and internal dripping elements presenting the features stated in claims 1 and 4. In the preambles of claims 1 and 4 have been set forth the common features disclosed in IT-A-1,255,120.

Further improvements of the invention are disclosed in the dependent claims.

The invention provides several important advantages.

Due to the fact that in each dripping element having a hollow box-like body in the bottom thereof is provided a single filter zone and a single flow path, having a meandering labyrinth-shaped development which creates an efficient self-cleaning action it is therewith possible to confer to the dripping elements a strip-like configuration with small dimensions. This permits on the one hand to obtain lighter and cheaper dripping elements and to facilitate on the other hand the thermo-welding process because the surface to be welded is reduced, as well as to reduce the welding process time.

The smaller strip-like area of the dripping elements to be thermo-welded to the internal hose surface allows said dropping elements to be used for a greater range of hose diameters.

The achieved self-cleaning of the flow path permits to avoid a clogging of the latter, and this, together with the suggestion of

perforating all provided discharging chambers during the manufacturing of the irrigation hose, makes the known surveillance inspections superfluous.

Further, the provision of perforations in all provided discharging chambers allows a real enlargement of the irrigated land surface as well as a greater and quicker water distribution in the soil. At the same time a reduction of the percolation on the hose is reached because the outgoing flow is divided in more delivering paths.

Another advantage is to be seen in the fact that after an irrigation cycle a total emptying of the dripping elements is achieved and this considerably reduces the risk of bio-clogging, that is the clogging which is due to the known dissolution or presence of bio-components in the irrigation water.

Brief description of the drawings

Further characteristics, advantages and details of the drop-by-drop irrigation hose and dripping elements according to the invention will become more apparent hereinafter from the following disclosure of a drop-by-drop irrigation hose with internal dripping elements according to the invention which are schematically illustrated, by way of an indicative example, in the accompanying drawing in which are represented several figures, drawn on different scales, and where:

Figure 1 is a view on a section of the drop-by-drop irrigation hose according to the present invention;

Figure 2 shows a the detail A of Figure 1 on an enlarged scale;

Figure 3 is a cross-sectional view taken along line III-III of Figure 2; and

Figure 4 is a top plan view on a dripping element according to the invention on an enlarged scale.

Description of the preferred embodiment

Reference is made to the Figures in which a section of a drop-by-drop irrigation hose is denoted by 1 wherein said hose 1 is, for example, a flexible pipe or hose on the internal surface of which a number of dripping elements 2 are thermo-welded which are spaced by the pitch T.

According to the present invention said dripping elements 2 have the conformation of a strip-like hollow parallelepiped having a bottom 3, wherein the top wall of the dripping element is omitted because it will be formed by the internal surface of the hose 1 after having perimetrically thermo-welded said dripping element 2 to said hose internal surface, in a known manner.

In the bottom 3 is provided a perforated zone 4 defining a filter structure. According to the present invention more discharging chambers 5 are provided. In the shown example are provided two discharging chambers 5 at the ends of said dripping element 2. A meandering flow path is denoted by 6.

As inferable from Figure 4, the meandering flow path 6 is in communication at one end with said filter 4 through the opening 10 and at the other end with a channel 8 through the opening 7, wherein said channel 8 opens at both ends thereof in an end discharging chamber 5, respectively. The arrows F show the partitions of the water flow coming from the winding labyrinth-like flow path 6 towards said discharging chambers 5. In the shown example to both discharging chambers 5 will be substantially delivered the same water amount by said channel 8. Holes or perforations in the hose 1 above the underlying discharging chambers 5 are denoted by 9.

As said perforations 9 through the hose wall above all provided discharging chambers 5 are made during the extrusion of said hose 1, the perforations 9 may be provided with any desirable pitch T as chosen for the dripping elements 2, and it is therefor no more

necessary to form the known "depressions" in the irrigation flexible pipe 1.

The chosen narrow strip-like box-like design of the dripping elements 2 is clearly inferable from the Figures 3 and 4. Said
5 dripping elements 2 are placed consecutively along a common generating line of the hose 1, so that with the positioning thereof on the land as shown in the drawing a total emptying of said dripping elements 2 after each irrigation cycle will be reliably achieved.

During irrigation the water flowing in the hose 1 will flow on the
10 bottom 3 of said dripping elements 2 and enter therein through the filter 4. From said filter 4 the irrigation water will flow along the meandering flow path 6 with formation of turbulences therein – and corresponding self-cleaning action in said meandering flow path 6 – up to said channel opening 7 and subsequent water partition in both
15 branches of said channel 8 and enter the perforated discharging chambers 5. The water will then leave said discharging chambers 5 drop-by-drop and water the soil in a number of areas, in the shown example in two areas.

If a discharging chamber 5 in the suggested dripping elements 2
20 should become clogged, the irrigation will continue with the other provided discharging chamber/chambers 5.

From the above constructional and operating disclosure, it should be apparent that with the teaching according to the present invention to provide a single filter 4, a single meandering flow path
25 6, as well as two or more discharging chambers 5, which latter are all perforated during the manufacturing of the irrigation hose 1, it is possible to efficiently achieve the indicated aims and the mentioned advantages.

In practicing the invention, one skilled in the art can perform
30 technical and/or functional equivalent modifications or variations concerning the single parts of the dripping elements 2 according to the present invention without departing from the scope of the

invention.

The present example, therefore, is to be considered in all respects as illustrative and not restrictive, and the invention is not to be limited to the details given herein.

Claims

1. A drop-by-drop irrigation hose consisting of plastic and having a
5 number of internal hollow plastics dripping elements having a
hollow box-like body and spaced from each other by a pitch, and
thermo-welded to the internal surface of said irrigation hose along
the top of said dripping elements, wherein in the bottom of said
dripping elements are provided a filter means in communication
10 with discharging chambers which are formed between said bottom
and the internal hose surface, characterized by the combination of
the following features:
- i) said filter means is formed by a single filter (4),
 - ii) said filter (4) is in communication with a labyrinth-like flow path
15 (6) which simultaneously opens in a number of discharging
chambers (5), and
 - iii) all the provided discharging chambers (5) are in communication
with the hose external environment by means of one or more holes
(9) through the hose wall,
 - 20 said hose (1) being either a circular flexible pipe or a flat hose.
2. An irrigation hose according to claim 1, characterized in that
said labyrinth-like flow path (6) opens in two discharging
chambers (5)
25 which are provided at the ends of said dripping elements (2).
3. An irrigation hose (1) according to claim 1 and 2, characterized
in that said filter (4) is provided in a middle area of the dripping
element bottom (3) and said single labyrinth-like flow path (6)
30 develops along two parallel longitudinal branches.
4. A dripping element for drop-by-drop irrigation hose presenting

an hollow body as well as a filter means in communication through a flow path with discharging chambers characterized in that it presents the features set forth in one or more of the preceding claims 1 to 3.

5

5. A dripping element according to claim 4, characterized in that it presents a strip-like configuration.
